Introduction

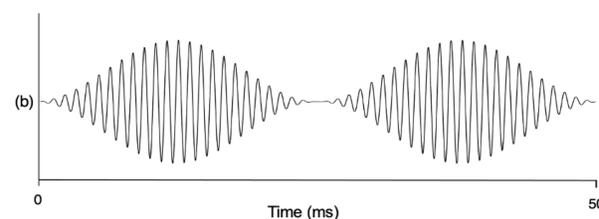

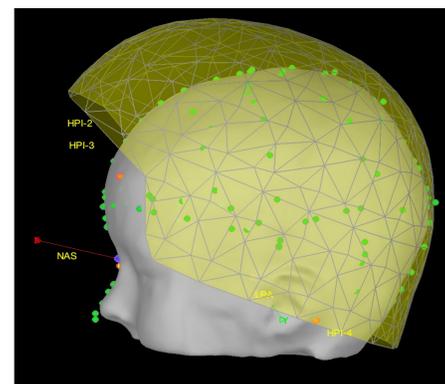

- Abnormal language development occurs in most children with Autism Spectrum Disorder (ASD), although language impairment is not a core symptom of ASD.
- Neural mechanisms of language impairment in ASD are still poorly understood.
- Cortical gamma-band abnormalities are considered by some authors as one of the common pathophysiological mechanisms in ASD.

Objectives

- The goal of the present study is to investigate whether auditory gamma oscillations, measured with 40 Hz Auditory Steady-State Response (ASSR), is related to language development in children with ASD.

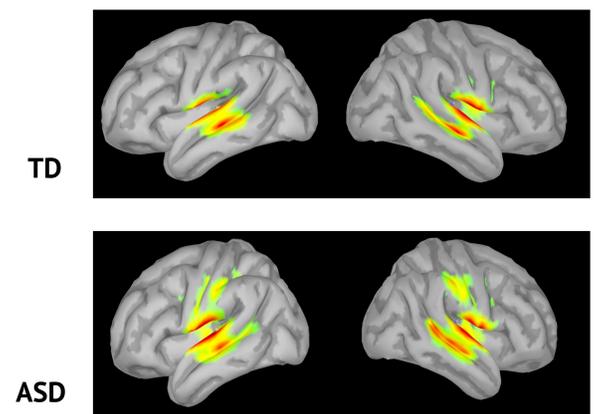

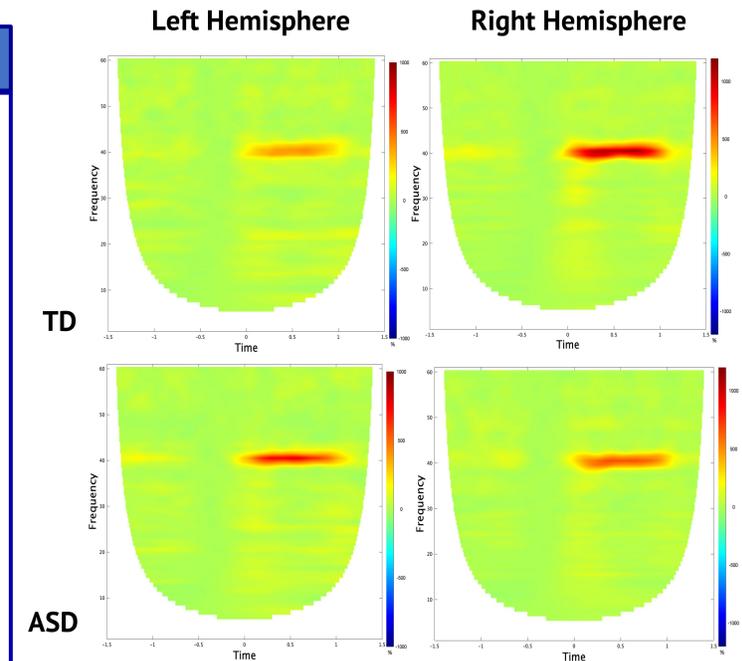

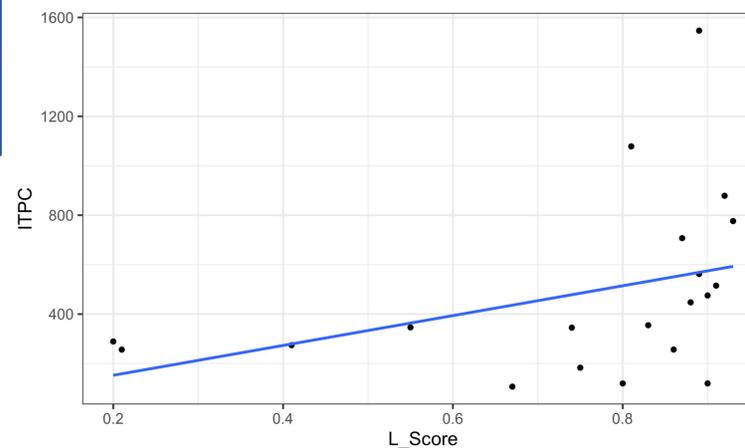

Methods

- 40 children participated in the study: 20 children with ASD (5 girls, age range 8–14), varying in non-verbal IQ (range 40 – 125), and a control group of 20 typically developing children, TD (9 girls, age range 7–12).
- Language abilities were measured with the Russian Child Language Assessment Battery; non-verbal IQ was screened with the Kaufman Assessment Battery for Children - II, and Wechsler Intelligence Scale for Children – Third Edition; the severity of autistic traits was measured with the Autism Spectrum Quotient: Children’s Version, AQ.
- Stimulus: 1000Hz pure tone with 1000 ms duration and 40Hz amplitude modulation (90 repetition).

Results

- We estimated MNI coordinates of ASSR response (x, y, z) for 2 groups of children, and there were no any differences in the sources of response.
- Linear-mixed effects model with nested contrast (ASD vs. TD):
 $\text{mod} \leftarrow \text{lmer}(\text{ITPC} \sim 1 + \text{Hemisphere}/\text{Group} + (1 | \text{ID}), \text{data} = \text{ASD}, \text{control} = \text{lmerControl}(\text{optimizer} = \text{"bobyqa"}))$.
- Spearman’s correlations (ITPC ~ Language, IQ, AQ, ADOS, Age) for both hemispheres.
- Only Language score correlated with ITPC and only in the left auditory ROI ($R = 0.56, p = 0.008$).

Fixed effects:

	Estimate	Std. Error	df	t value	Pr(> t)
